

**NPTEL MOOC**

# **PROGRAMMING, DATA STRUCTURES AND ALGORITHMS IN PYTHON**

**Week 2, Lecture 5**

**Madhavan Mukund, Chennai Mathematical Institute**

**<http://www.cmi.ac.in/~madhavan>**

# A typical Python program

```
def function_1(..,..):  
    ...  
def function_2(..,..):  
    ...  
    :  
def function_k(..,..):  
    ...  
  
statement_1  
statement_2  
    :  
statement_n
```

- \* Interpreter executes statements from top to bottom
- \* Function definitions are “digested” for future use
- \* Actual computation starts from `statement_1`

# Function definition

```
def f(a,b,c):  
    statement_1  
    statement_2  
    ..  
    return(v)  
    ..
```

- \* Function name, arguments/parameters
- \* Body is indented
- \* `return()` statement exits and returns a value

# Passing values to functions

- \* Argument value is substituted for name

```
def power(x,n):  
    ans = 1  
    for i in range(0,n):  
        ans = ans*x  
    return(ans)
```

```
power(3,5)  
  ↓  
x = 3  
n = 5  
ans = 1  
for i in range..
```

- \* Like an implicit assignment statement

# Passing values ...

- \* Same rules apply for mutable, immutable values
  - \* Immutable value will not be affected at calling point
  - \* Mutable values will be affected

# Example

```
def update(l,i,v):  
    if i >= 0 and i < len(l):  
        l[i] = v  
        return(True)  
    else:  
        v = v+1  
        return(False)
```

```
ns = [3,11,12]
```

```
z = 8
```

```
update(ns,2,z)
```

```
update(ns,4,z)
```

\* ns is [3,11,8]

\* z remains 8

- \* Return value may be ignored
- \* If there is no `return()`, function ends when last statement is reached

# Scope of names

- \* Names within a function have local **scope**

```
def stupid(x):  
    n = 17  
    return(x)
```

```
n = 7  
v = stupid(28)  
# What is n now?
```

- \* `n` is still 7
  - \* Name `n` inside function is separate from `n` outside

# Defining functions

- \* A function must be defined before it is invoked

- \* This is OK

```
def f(x):  
    return(g(x+1))
```

```
def g(y):  
    return(y+3)
```

```
z = f(77)
```

- \* This is not

```
def f(x):  
    return(g(x+1))
```

```
z = f(77)
```

```
def g(y):  
    return(y+3)
```

# Recursive functions

- \* A function can call itself — **recursion**

```
def factorial(n):  
    if n <= 0:  
        return(1)  
    else:  
        val = n * factorial(n-1)  
        return(val)
```

# Summary

- \* Functions are a good way to organise code in logical chunks
- \* Passing arguments to a function is like assigning values to names
  - \* Only mutable values can be updated
- \* Names in functions have local scope
- \* Functions must be defined before use
- \* Recursion — a function can call itself
